

Hashes and more about certificates

CSE 468 Fall 2026
jedimaestro@asu.edu

How do you know who you're talking to when you do encryption?

Authentication and non-repudiation

What if your private key gets stolen?

Forward secrecy and future secrecy

Critical
Is not a Certification Authority

Why hash functions?

- Speed
 - Symmetric crypto is generally faster than asymmetric
 - Hashes are generally faster than either
- Error detection (*e.g.*, checksum)
- Security and privacy

Why cryptographic hash functions?

- Unique identifier for an object
- Integrity of an object
 - *E.g.*, message authentication codes
- Digital signatures
 - Sign the digest
 - *E.g.*, 1024-bit RSA, 100MB message, 256-bit digest
- Passwords
- Proof of work

<https://en.wikipedia.org/wiki/HMAC>

Hash function example

What makes a hash function cryptographic?

- One-way function
- Deterministic (same input, same output)
- Infeasible to find message that digests to specific hash value
- Infeasible to find two messages that digest to the same hash
- Avalanche effect (small change in message leads to big changes in digest---digests seemingly uncorrelated)
- *Still want it to be quick*

Example algorithms

- MD5: 128-bit digest
 - seriously broken
- SHA-1: 160-bit digest
 - not secure against well-funded adversaries
- SHA-2: 224 to 512 bit digest
 - Merkle–Damgård construction
- SHA-3: 224 to 512 bit digest
 - Sponge construction
 - adopted in August of 2015
- CRC32: not cryptographic, very poor choice

Example algorithms

- MD5: 128-bit digest, seriously broken
- SHA-1: 160-bit digest, not secure against well-funded adversaries
- SHA-3: 224 to 512 bit digest, adopted in August of 2015
- CRC32: not cryptographic, very poor choice

Property #1

- Pre-image resistance
- Given h , it should be infeasible to find m such that $h = \text{hash}(m)$

Neither MD5 nor SHA-3 are broken in this way, but MD5 digests are small.

Property #2

- Second pre-image resistance
- Given a message m_1 , it should be infeasible to find another message m_2 such that...
 $hash(m_1) = hash(m_2)$

Neither MD5 nor SHA-3 are broken in this way, but MD5 digests are small.

Property #3

- Collision resistance
- It should be infeasible to find two messages, m_1 and m_2 such that...
 $hash(m_1) = hash(m_2)$

SHA-3 is not broken in this way, MD5 broken in seconds on your laptop, SHA-1 with \$100K or so.

Wang Xiaoyun

- Tsinghua University
- Contributed a lot of ideas to cracking MD5, SHA-0, and SHA-1

Length extension attack

```
jedi@mariposa:~$ echo "password='lDEnr45#d3'&donut=choc&quantity=1" | md5sum
91a9fc74a98997dba291a26a91c9648e  -
jedi@mariposa:~$ echo "password='lDEnr45#d3'&donut=choc&quantity=100" | md5sum
8fdd2d4515bcba887b1b80a653f21e0c  -
```

```
jedi@mariposa:~$ echo "password=[REDACTED]'&donut=choc&quantity=1" | md5sum
91a9fc74a98997dba291a26a91c9648e  -
jedi@mariposa:~$ echo "password=[REDACTED]'&donut=choc&quantity=100" | md5sum
8fdd2d4515bcba887b1b80a653f21e0c  -
```

MD5 and SHA-1 vulnerable, SHA-2 basically is, SHA-3 is not

Length extension attack

- One issue is if the attacker doesn't know the password
- Another issue is if the password is different but the attacker finds a collision later on

MD5

- Pad to multiple of 512 bits
- 4 rounds
- 4 32-bit words at a time
- Concatenate them at the end for a 128-bit digest
- F is non-linear, varies by round

Round (i)	$F(X, Y, Z)$	g
0	$(X \wedge Y) \vee (\neg X \wedge Z)$	i
1	$(X \wedge Z) \vee (Y \wedge \neg Z)$	$(5 \times i + 1) \bmod 16$
2	$(X \oplus Y \oplus Z)$	$i(3 \times i + 5) \bmod 16$
3	$(Y \oplus (X \vee \neg Z))$	$(7 \times i) \bmod 16$

SHA-3

- Sponge construction, 1600 bits of internal state

<https://en.wikipedia.org/wiki/SHA-3>

Review: Birthday attack

- Probability of collision is 1 in 2^n , but the expected number of hashes until two of them collide is $\sqrt{2^n}=2^{n/2}$
 - Why? Third try has two opportunities to collide, fourth has three opportunities, fifth has six, and so on...

24 people, same birthday?

Chosen-prefix collision attack

- Given two prefixes p_1 and p_2 , find m_1 and m_2 such that $hash(p_1 || m_1) = hash(p_2 || m_2)$
- p_1 and p_2 could be domain names in a certificate, images, PDFs, *etc.* ... any digital image.

Ingredients for a practical chosen prefix attack on MD5

- Collision attack on MD5
 - That works for any initialization vector (so you can put bits in front)
- Length extension attack
 - So you can put identical bits on the end
- Birthday attack
 - So you can bridge the prefix to a block that meets the requirements of the collision attack

MD5 collision attack by Wang and Yu

$$C_0 = (0, 0, 0, 0, 2^{31}, 0, 0, 0, 0, 0, 0, 2^{15}, 0, 0, 2^{31}, 0)$$

and

$$C_1 = (0, 0, 0, 0, 2^{31}, 0, 0, 0, 0, 0, 0, -2^{15}, 0, 0, 2^{31}, 0)$$

Fig. 1. One MD5 step

Round (i)	$F(X, Y, Z)$	g
0	$(X \wedge Y) \vee (\neg X \wedge Z)$	i
1	$(X \wedge Z) \vee (Y \wedge \neg Z)$	$(5 \times i + 1) \bmod 16$
2	$(X \oplus Y \oplus Z)$	$i(3 \times i + 5) \bmod 16$
3	$(Y \oplus (X \vee \neg Z))$	$(7 \times i) \bmod 16$

Short Chosen-Prefix Collisions for MD5 and the Creation of a Rogue CA Certificate

Marc Stevens¹, Alexander Sotirov²,
Jacob Appelbaum³, Arjen Lenstra^{4,5}, David Molnar⁶,
Dag Arne Osvik⁴, and Benne de Weger⁷

legitimate website certificate		rogue CA certificate	
serial number	chosen prefixes	serial number	1024 bit RSA public key
commercial CA name		commercial CA name	
validity period		validity period	
domain name	collision bits	rogue CA name	v3 extensions "CA = TRUE"
2048 bit RSA public key			
v3 extensions "CA = FALSE"	identical suffixes	tumor	

Fig. 1. The to-be-signed parts of the colliding certificates
